The durability of alumina supported Pd catalysts for the combustion of methane in the presence of SO₂

In the present work, the 1 wt% Pd/Al₂O₃, 1 wt% Pd/10 wt% CeO₂/Al₂O₃ and 1 wt% Pd/10 wt% Ce₀.6Zr₀.4O₂/Al₂O₃ catalysts were prepared and used for the catalytic combustion of methane. The durability of the catalysts were investigated based on the phenomena of SO₂ poisoning in methane catalytic combustion. The presence of SO₂ in the reaction gases resulted in a 70-250 °C increase of light-off temperature for methane conversion for all tested catalysts. Pre-treatment of the catalysts with SO₂ also led to a decrease in catalytic activity to some extent. The sulphur poisoning and sulphate formation were mainly responsible for the catalyst deactivation. The PdO species contributed to the formation of sulphates by oxidizing SO₂ to SO₃ species. The sulphates were formed below 600 °C and decomposed above 600-700 °C in the reactions over the catalysts, which led to the inhibition and recovery of the catalytic activity, respectively. The effluent gases (SO₂, SO₃, and O₂) of the SO₂-TPD experiments were monitored on-line by a mass spectrometer (Hiden HPR-20 QIC). The results indicated that the introduction of CeO₂ or Ce₀.6Zr₀.4O₂ decreased the decomposition temperature of sulphates by 50-100 °C. Sulphur accumulation on the catalyst surface was investigated by sulphur content analysis and TG measurements after pre-treatment with SO₂. The saturated sulphur contents were all about 5 wt% for the three catalysts. In spite of sulphur poisoning, no obvious changes in the particle morphologies or dimensions were observed for the fresh and used catalysts. The introduction of CeO₂ or Ce₀.6Zr₀.4O₂ decreased the decomposition temperature of sulphates by 50-100 °C, indicating that the durability of the catalysts studied in this work could be satisfied for the catalytic combustion of methane that usually takes place above 800 °C.

HPR-20 QIC Real time Gas Analyser

FIGURE 1 (OPPOSITE): Simplified schematic illustration of the in-house built catalytic rig used to mimic exhaust conditions and perform selective catalytic reduction of NO in the presence of NH₃. All gas lines used were stainless steel grade. All (red colored) lines between the MFC’s and analysis instruments (via the reactor) were heated using electrical heat tracing and insulated using quartz wool bands. The electronics, including controls for the MFC units, heating for the gas lines and oven are excluded for clarity. The whole setup can be interfaced into one computer using commercially available lab-view software for automation of the running process. The analytical instruments can work as stand-alone (as in this case) for ease of individual software use, or can be interfaced together with the rest of the setup. Towards the right bottom is an extended illustration of the use of a similar setup at synchrotron beamlines 1 for performing in situ/operando type experiments. Samples can be placed in a capillary (to mimic plug-flow conditions), and connected to a MS at the end for online product analysis. X-ray absorption/X-ray diffraction data can be collected in sequence as a function of reaction conditions.
Structure-performance relationships of Cu based porous catalysts for selective catalytic reduction (SCR) of NO\textsubscript{x} gases from diesel exhausts

The aim of this project is to obtain a fundamental understanding of Ammonia-Selective Catalytic Reduction (NH\textsubscript{3}-SCR) systems commonly used for emission abatement in heavy duty diesel vehicles. An important aspect of the work involves synthesis of various copper exchanged zeolites using different preparation techniques. The catalysts are pre-characterized using conventional laboratory techniques such as UV-Vis spectroscopy and X-ray diffraction. The materials are further tested for their catalytic activity using an in-house built catalytic rig under plug-flow conditions. The output gasses are analysed online using infra-red spectroscopy and a Hiden Analytical, HPR-20 QIC bench top gas analysis system. Fast and continuous monitoring of the output gases allows for the determination of activity/selectivity profiles of catalysts in question.

The catalysts are further analysed using synchrotron light sources under in situ NH\textsubscript{3}-SCR reaction conditions. Catalysts are loaded into quartz capillaries connected to a pre-set gas rig. The output gasses are continuously monitored using mass spectrometry to obtain accurate information on the conversion profiles. The pre-determined positions of cations within zeolites make it possible to combine both long and short range probing techniques to yield information on the structure and co-ordination of the active sites. To that end, combined X-ray absorption and X-ray diffraction data are collected at different temperatures under SCR conditions which help elucidate the local Cu environment in these catalysts.

In this particular case-study, an attempt was made at tailoring the active sites in Cu-CHA based catalysts. Three different synthetic routes were adapted to achieve this goal: two methods are based on post-synthetic treatment of the zeolite material (via aqueous or vapour phase) and a third one involving the direct synthesis of a Cu-loaded SAPO-34. Product analysis under SCR conditions revealed that whilst the catalyst materials prepared via wet chemical routes show excellent deNO\textsubscript{x} activity and high selectivity to N\textsubscript{2}, the one prepared via chemical vapour deposition gave the undesired product N\textsubscript{2}O in significant quantities. Isolated mononuclear Cu\textsuperscript{2+} ions in the vicinity of six-membered rings (6\text{mr}s, part of the d6r sub-units of CHA) were found to be active sites in both catalyst materials prepared via the wet chemical approaches. In contrast, the catalyst prepared via chemical vapour deposition possesses Cu in two different environments: isolated Cu\textsuperscript{2+} cations and CuAlO\textsubscript{2}-type species. Catalytic experiments revealed a strong correlation between the number of isolated mononuclear Cu\textsuperscript{2+} in or near the plane of the 6\text{mr}s and N\textsubscript{2} production, whereas the presence of CuAlO\textsubscript{2} species appears to promote the formation of undesired N\textsubscript{2}O.

HPR-20 QIC Real time Gas Analyser
The effect of heating rate on porosity production during the low temperature reduction of graphite oxide

Thermal reduction conditions play a crucial role in the evolution of porosity during the thermal reduction of graphite oxide at low temperatures. Higher heating rates increase the porosity of the TH-rGO. A slow heating rate facilitates the evolution of H₂O and CO₂ whereas a higher heating rate releases CO₂ and CO gases with the concurrent development of a folded and crumpled morphology, investigated by using mass spectroscopy (HPR-20; Hiden Analytical). More importantly, the reduction time and temperature are found to be dependent on the heating rate. High heating rates shortened the reduction time (less than 5 min in ≥ 10 °C/min⁻¹) with lower reduction temperature (below 140 °C), whereas higher temperatures and longer times were required to complete the reduction reaction at low heating rates. With the results it may be possible to rationally design the pore textures and chemical structure of the chemically-reduced graphite oxide to fit a variety of end-uses, particularly in electrochemical energy storage, adsorbents, and conductive/reinforced carbon nanocomposites.
Our research project concerns the H₂S abatement from a biogas stream to feed to molten carbonate cells (MCFC) for energy production.

Biogas is a renewable energy source that can be produced from biomass, agricultural and industrial waste and sewage sludge. Its main constituents are CH₄, CO₂ but unfortunately sulphur based compounds are present as H₂S, COS.

The main limitation to the use of biogas as fuel in these systems is linked to the presence of sulphur compounds such as H₂S that can poison the fuel cells components, anode and electrolyte.

For the small scale plant, a very interesting solution can be represented by the direct and selective H₂S oxidation to sulphur at low temperature by using a suitable catalyst.

The aim of the work is the study of the catalytic behavior of V₂O₅/CeO₂ samples at various vanadium loading (2.55 - 20 wt % as V₂O₅) to determine the optimal catalyst formulation and operating conditions to obtain a very high H₂S conversion and the SO₂ selectivity minimisation.

The catalytic tests were carried out in a fixed bed flow reactor, made of a steel tube 21 cm long and a 14 mm of internal diameter. The reactor is inserted in an electrical furnace equipped with a PID electronic temperature controller. A thermocouple is inserted in a steel sheath of the inner diameter of 6 mm concentric to the reactor.

Catalytic activity tests were carried out at atmospheric pressure and GHSV=9.5·10⁴ h⁻¹ (40 ms), in the temperature range 150 – 250 °C, by feeding a mixture of 200 ppm of H₂S, 100 ppm of O₂ and N₂ to balance (see Fig. 1). The exhaust system was equipped with a sulphur trap and analysed by a quadrupole mass spectrometer (Hiden Analytical, HPR-20 QIC). Figure 2 shows typical behaviour of a catalytic activity test carried out by using a catalyst using the highest vanadium loading (20%). With this condition being the optimal catalytic performance and more selective to sulphur (99%) at lower temperature.

It can be seen from the data above, in the first 10 minutes of the experiment, that the feed stream was added in the by-pass position to stabilise the initial concentrations of H₂S and O₂. After this time, the feed stream was sent to the reactor, and large increases in the concentrations of H₂S, SO₂, and O₂ were observed. After a further 10 minutes the concentrations stabilised, showing high activity and stability of the catalyst.

The H₂S and O₂ conversions were 97 and 98% respectively, while the SO₂ concentration remained very low (~1%).
The development of new solid acid and base catalysts depends on the availability of suitable catalyst characterisation techniques. One of the accepted methods for characterising surface acidity and surface basicity is adsorption calorimetry, using probe compounds to study the concentration and strength of active sites. For solid acids a basic probe such as NH₃ is used, and for solid bases acidic probes such as SO₂ or CO₂ are used.

HPR-20 QIC Real time Gas Analyser

The system is shown in Figure 1 and example data from an experiment in which NH₃ is introduced to a solid acid catalyst is shown in Figure 2.

The usefulness of this data in characterising solid acid catalysts is illustrated in Figure 3, where profiles of -ΔH_{ads}(NH₃) vs amount of NH₃ adsorbed are shown for a series of polymer-supported sulfonic acid catalysts. The objective of this study was to investigate the relationship between catalyst structure and the concentration and strength of the surface acid sites. The catalysts range from Nafion SAC-13 with 0.1 -0.2 mmol g⁻¹ of acid sites of high strength, to Amberlyst 35 with over 5 mmol g⁻¹ of medium strength sites, to D-5081/2 with approximately 1 mmol g⁻¹ of lower strength sites. This information can be related to the catalytic activities of these materials and can be used in a synthetic programme of catalyst optimisation.
Multicapacity Microreactor for Catalyst Characterisation

The Hiden Catlab integrated microreactor/mass spectrometer (MS) system now addresses an extended applications range with the introduction of enlarged sample capacity options to accommodate sample volumes up to 2 mL. The system, developed for quantification of catalytic activity and thermal reaction processes in both R&D and QC laboratories, monitors gas and vapour reaction products directly from the sample position via the primary sampling interface embedded within the 1000 °C fast-response furnace. The interface concept maintains optimum system performance throughout the full sample capacity range down to 0.1 mL, with the cartridge-style sample holders enabling fast and accurate sample placement.

In the press:

LabVIEW-based software is fully user-programmable to define the furnace temperature profile and ramp rate, establish MS data acquisition parameters, input gas/vapour flow through up to 8 mass flow controllers (MFC’s), and select valve switching functions including pulse gas injection for chemisorption measurement. The temperature profile determines the trigger-points to change gas composition, to inject gas pulses and to stop/start data acquisition. Additionally MS analysis files can be selected and matched to specific sections of the experiment to ensure optimum data at each stage.

The CATLAB system is engineered for combined reactor/MS system operation yet is readily decoupled to enable operation of the mass spectrometer as a standalone laboratory and process gas analyser, a secondary interface providing a decoupling point for off-line MS operation.
Hiden's quadrupole mass spectrometer systems address a broad application range in:

**GAS ANALYSIS**
- dynamic measurement of reaction gas streams
- catalysis and thermal analysis
- molecular beam studies
- dissolved species probes
- fermentation, environmental and ecological studies

**SURFACE ANALYSIS**
- UHV TPD
- SIMS
- end point detection in ion beam etch
- elemental imaging - surface mapping

**PLASMA DIAGNOSTICS**
- plasma source characterisation
- etch and deposition process reaction kinetic studies
- analysis of neutral and radical species

**VACUUM ANALYSIS**
- partial pressure measurement and control of process gases
- reactive sputter process control
- vacuum diagnostics
- vacuum coating process monitoring
